

A mechanism for the transition: translation rows make agreement self-reinforcing, and the feedback loop closes only above a critical tr ($c=8$, 8-256, $wd=0$, constant LR)

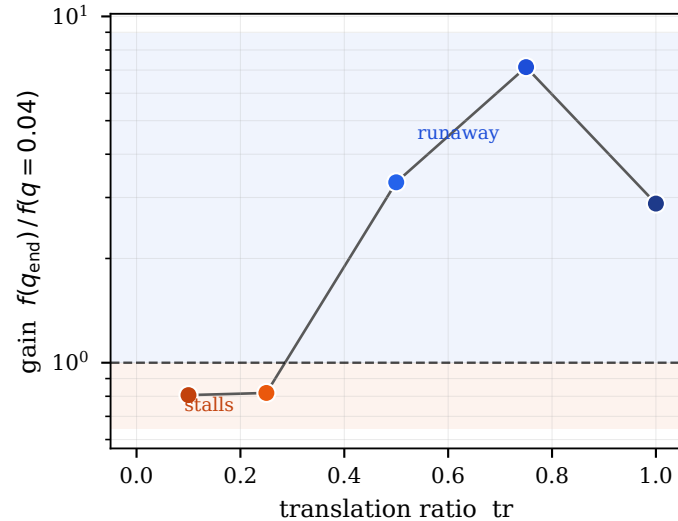

(A) the order parameter, from weights alone

(B) flow vs state: rising = autocatalytic, falling = stalling (dot = end of run)

(C) gain crosses 1 between $tr=0.25$ and $tr=0.50$ — the transition

(D) the trunk builds agreement, the last block tears it down
