

Why translation ratio has a threshold: translation rows make agreement self-reinforcing, and the loop only closes above $\text{tr} \approx 0.25\text{-}0.5$ ($c=8$, $8\text{-}256$, $\text{wd}=0$, constant learning rate)

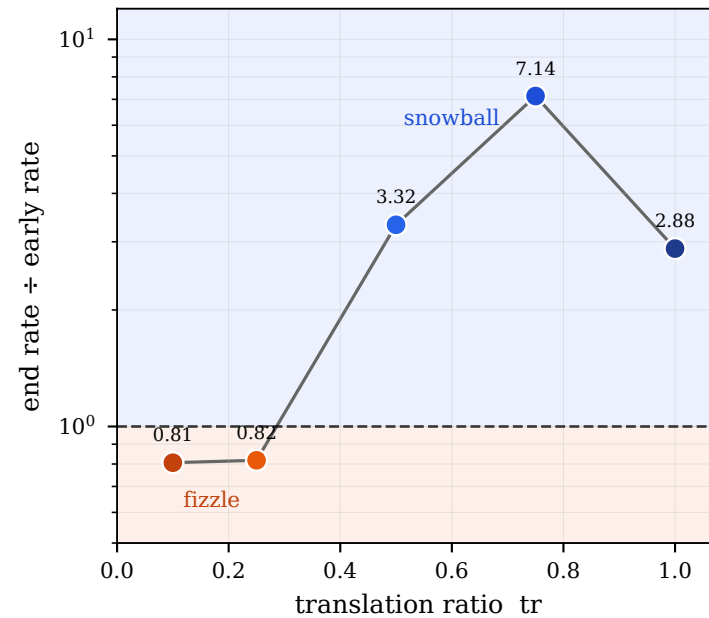

(A) Do the 8 compartments agree on how to encode a token?

(B) As they agree more, does agreement speed up or slow down?

(C) The tipping point sits between $\text{tr} = 0.25$ and $\text{tr} = 0.5$

(D) Agreement is built through the trunk, then undone at the very end
