

Does $\text{tr}=0.25$ transition later, or not at all? $c=8$, 8-256, constant LR (no decay) — 1M steps cannot settle it

(A) the delay grows with the threshold
a constant delay would give one number

(B) best single shift still misfits
 $\text{rmse } 0.039 = 25\%$ of the fitted range

(C) $\text{tr}=0.25$ is accelerating where $\text{tr}=0.5$
is saturating — the foot of a sigmoid?
